UNIVERSITY

## Section B

---

Principles, Standards, and Challenges

# Principles and Characteristics of “Perfect” Identifier

- *Accessible*: available when required
- *Assignable*: by a trusted authority after a properly authenticated request
- *Atomic*: single data item with no sub-elements having separate meanings
- *Concise*: as short as possible

# Principles and Characteristics of “Perfect” Identifier

- *Content-free*: no dependence on possibly changing or unknown information
- *Cost-effective*: maximum functionality with minimum investment to create and maintain
- *Controllable*: only trusted authorities have access to linkages between encrypted and non-encrypted identifiers
- *De-identifiable*: ability to create a number of encrypted identifiers with same properties

# Principles and Characteristics of “Perfect” Identifier

- *Governed*: has entity responsible for overseeing system
- *Incremental*: capable of being phased in
- *Linkable*: can link health records together in both automated and manual systems
- *Mappable*: able to create bidirectional linkages between new and existing identifiers

# Principles and Characteristics of “Perfect” Identifier

- *Mergeable*: can merge duplicate identifiers to apply to the same individual
- *Networked*: supported by a network that makes services available universally
- *Permanent*: never to be reassigned, even after a holder’s death
- *Portable*: can be moved from system to system

# Principles and Characteristics of “Perfect” Identifier

- *Retroactive*: can assign identifiers to all existing individuals when system is implemented
- *Secure*: can encrypt and decrypt securely
- *Scalable*: can be used at various levels of technology capabilities
- *Standard*: compatible if possible with existing or emerging standards

# Principles and Characteristics of “Perfect” Identifier

- *Technology-neutral*: can be used with different types of technology
- *Unambiguous*: minimizes misinterpretation risks
- *Unique*: identifies one and only one individual or entity
- *Universal*: applies across boundaries
- *Usable*: processable by both manual and automated means
- *Verifiable*: can determine validity without additional information

# National Health Standards for Unique Identifiers

- Standards for individuals
    - Individual providers
    - Patients
    - Others
  
  - Standards for organizations
    - Provider organizations
    - Payers
    - Employers
    - Others
- 
- Standard identifier for systems and processes
  
  - Standard identifier for devices

# The National Provider ID (NPI)

- Established under HIPAA in 2004
- Defined as a unique randomly assigned national 10-digit (all-numeric) identifier
  - No “intelligence” built into number
  - Last digit = “Check-Digit” to validate integrity of number
  - First digit expected to be limited to a 1, 2, 3, and 4
    - ▶ Each sequence (i.e., all numbers starting with a 1) will allow for up to 100 million numbers (1234567891)
    - ▶ All numbers assigned to date start with a 1

# The National Provider ID

- Issued by federal government (HHS)
  - National Payer and Provider Enumeration System (NPPES)
  - <https://nppes.cms.hhs.gov>
- Applies to all individual health care providers and provider organizations subject to HIPAA
- Required to be used on electronic transactions

# The National Provider ID

- Will replace all other “proprietary” provider identifiers (assigned by payers and others)
- Will not replace other identifiers such as the TaxID, the state license number, the DEA number

# The National Provider ID

- Providers eligible to obtain an NPI
  - Must meet the definition of “health care provider” under HIPAA
  - Individual health care providers include physicians, dentists, psychologists, therapists, nurses (not all), chiropractors (not all), and many other health care providers

# The National Provider ID

- Providers eligible to obtain an NPI
  - Must meet the definition of “health care provider” under HIPAA
  - Individual health care providers include physicians, dentists, psychologists, therapists, nurses (not all), chiropractors (not all), and many other health care providers
  - Provider organizations include hospitals, clinics, pharmacies, long-term facilities, home health, etc.
  
- Enumeration started May, 2005
  - 2.4 million NPIs issued
    - ▶ 1.9M individuals
    - ▶ 0.5M organizations
  
- Required to begin to be used by May, 2008

# The National Payer ID

- Each health plan needs to be identified in health care transactions
- Health plans offer multiple plan products
- Consumers enroll in specific plan products
- Providers “enroll” into specific health plan’s provider network via contracts
- Consumers and providers relate to each other via a plan product
- Potential need to identify at a more granular level (plan product)

# The National Payer ID

- Status of standard
  - Being established under HIPAA
  - National Committee on Vital and Health Statistics held hearings and submitted recommendations to HHS on the adoption of a Plan ID
  - Currently CMS is preparing the proposed regulations that will establish the standard
  - Expected to enumerate every legal health plan entity plus some plan product component level
    - ▶ Medicare, Medicaid, commercial, self-insured products
  - Expected to also be a 10-digit identifier (following the NPI enumeration system)
  - Expected to use NPES for enumeration
  - Numbers could start with 7, 8, or 9 to avoid conflict with NPI

# The National Employer ID

- Employers also need to be identified into the health care system
- HIPAA established the standard for employer identification
  - Employer Identification Number (EIN)
  - Assigned to every legally established employer in the country
    - ▶ Except sole-proprietorships
  - Does not require any re-enumeration: it already exists, is assigned, and will continue to be assigned
  - A health care provider organization *is also* an employer (will have an EIN and an NPI)
  - Currently in place and being used in the health care system

# The National Patient ID

- The ultimate challenge: how to uniquely identify individual patients across multiple, disparate, external, and un-related systems
  - Between two providers
  - Between a provider and a payer
  - Between private and public sector, etc.
  - Across RHIOs
  - Across the NHIN?

# The National Patient ID

- Today's realities
  - Each provider assigns an ID to each patient (“medical record number”)
  - Each payer assigns an ID to each enrollee (“consumer enrollment ID”)
  - Employers generally use the Social Security number of employees
  - In some cases the same patient is assigned two or more IDs by a provider or a payer
  - Many provider and payer organizations have established “master patient indexes” and “record-linkage systems”
  - Regional networks establishing “record locator services”

# The National Patient ID

- Standards work to date
  - Initially to be developed by HHS as part of HIPAA
  - Congress de-funded the effort (in effect, stopping any efforts being done)
  - Some states exploring the adoption of a unique patient ID within the state

# The National Patient ID

- Shift in focus
  - Efforts moving away from unique IDs and into standard methods to achieve reliable and valid patient record matching and record linkages across organization, networks, and information exchanges
  - Office of National Coordinator implementing NHIN prototypes that included testing of methods and techniques to uniquely link records across organizations
  - Private entities promoting various methods for establishing a match between a patient and his/her records distributed across a network
    - ▶ Statistical Probabilistic Matching Method
    - ▶ Record locator service systems (RLS)
- Still much work to be done

# New and Emerging Health Standard Identifiers

- IP address
  - System identification
  - Security protections
    - ▶ I.e., identification, authentication, non-repudiation
  
- **Uniform resource identifiers (URI)**
  - Used in computing and networking to identify system resources and part of a larger Internet information architecture that is composed of:
    - ▶ *Uniform resource name (URN)*: used for identification of a resource
    - ▶ *Uniform resource characteristics (URCs)*: provides meta-data about resource
    - ▶ *Uniform resource locators (URL)*: provides location for finding resource

# New and Emerging Health Standard Identifiers

- OIDs
  - *Object identifier*: an identifier used to name an object
  - Hierarchical structure that includes a namespace defined using the ASN.1 (Abstract Syntax Notation One) of the ITU-T (International Telecommunications Union-Telecommunications Standardization Sector)
  - Assigned by country, by sector within country, and by authority within sector

## Bottom Line

- There are several components of the system that need to be uniquely identified (person, entity, system, device)
- Unique identifiers are a critical infrastructure/building block component of an interoperable health information system
- While standards exist, have been adopted, and are in use for information systems and devices, standards for uniquely identifying individuals and organizations are only beginning to be adopted and used

## Bottom Line

- There are important limitations on the National Provider Identifier system that will need to be addressed in order to achieve full, universal, ubiquitous status
- The unique patient identifier in the United States is not seen as a viable, realistic option yet
  - Instead, alternative patient identification systems are being considered
    - ▶ Including record linkage systems and probabilistic record matching methods

Thank You
